

the seam $\theta = 0$, where (i) cuts

(i) the angle chart: cut along $\theta = 0$, then identify the two edges. The rotating orbit is an *arc*. It closes only because the two edges are the same line of $\mathcal{M}$, so no single angle chart holds it: chart 2 covers the seam. $\oint p_\theta d\theta = 10.13$ is the area under it, not an enclosed area.

(ii) the trained encoder Ψ^{enc} : one chart, nothing identified, so *every* loop bounds. The librating loop bounds the blue region, which leaves γ_+ out; the rotating loop runs outside γ_- and takes γ_+ in. That patch is the step.
